Presenter

Juraci Paixão Kröhling

Software engineer

Agenda

The basics

- What's OpenTelemetry
- What's OpenTelemetry Collector
- Other related projects: contrib and builder

Deployment patterns

- General purpose patterns (basic, normalizer, per-signal)
- Patterns for Kubernetes (daemonsets, sidecars)
- Enterprise patterns (multi-cluster, multitenant, load balancing)

Advanced topics

- Assembling your own distribution
- Extending with your components

Questions and answers

What's OpenTelemetry

OpenTelemetry is a collection of tools, APIs, and SDKs. Use it to instrument, generate, collect, and export telemetry data (metrics, logs, and traces) to help you analyze your software's performance and behavior.

Standards, specifications, and conventions

Client instrumentation APIs and SDKs

Middleware

Standards, specifications, and conventions

OpenTelemetry API / SDK

Semantic conventions

OpenTelemetry Line Protocol

 For people looking to implement APIs and SDKs

 Which metadata to include in which operations Interface description language (IDL), specifying how data should look like and what endpoints should implement

@jpkrohling

Client instrumentation APIs and SDKs

OpenTelemetry API

OpenTelemetry SDK

Instrumentation libraries

 What you use on a daily basis to instrument your service

 What to do with the instrumentation: how to create the data, buffer, send out Libraries that will hook into parts of your stack and instrument it

Middleware

What's OpenTelemetry Collector

Vendor-agnostic way to receive, process and export telemetry data.

Patterns!

Pattern #1 - Basic I

Pattern #1 - Basic I

Good for:

- Abstracting where to actually send the telemetry data
- Doing extra-processing between your workload and the telemetry backend
- Avoid when:
- Well, when you don't need an extra processing layer, every extra hop is a chance for things to go wrong •

Pattern #1 - Basic II - Fanout

@jpkrohling

Pattern #1 - Basic II - Fanout

Good for:

- Trying out different open source solutions and/or vendors
- Retaining data ownership even when your main observability tool is a SaaS
- Avoid when:
- Processing tons of data: be conscious of the costs

Pattern #2 - Normalizer

Pattern #2 - Normalizer

Good for:

- Ensuring that different data points have the same semantics for the same things
- It's hard or undesirable to fix the problem at the source
- Avoid when:
- You have too many things to normalize. It might be better to try to \checkmark fix the problem at the source

Pattern #3 - Kubernetes - Sidecars

Ø

@jpkrohling

Pattern #3 - Kubernetes - Sidecars

Good for:

- Quickly offloading telemetry data from your application to a local process
- Fine-grained control over the configuration for each PodSpec or namespace
- Client-side load balancing is better when there are multiple of clients, especially for long-lived connections (HTTP/2, gRPC, Thrift, ...)

Avoid when:

- The overhead is not acceptable, as each sidecar needs at least ~20MiB of RAM
- You can't use something like the operator to manage the configs

Pattern #3 - Kubernetes - DaemonSets

@jpkrohling

Pattern #3 - Kubernetes - DaemonSets

Good for:

- Quickly offloading telemetry data from your application to a local process
- Less collector instances mean less maintenance and runtime overhead
- Avoid when:
- You need multi-tenancy
- It's not acceptable to lose telemetry data for all pods on a node in case of a crash with the local collector

Pattern #4 - Load balancing

6

Pattern #4 - Load balancing

Good for:

- Load balancing whole traces to collectors that need a complete view of the trace: span metrics processor, tail-based sampling, ...
- Avoid when:
- You just need a simple load balancing, without caring about the trace ID at all. For that, use a regular HTTP/2 or gRPC load balancer.

Pattern #5 - Multi-cluster

6

Pattern #5 - Multi-cluster

Good for:

- Centralizing your telemetry data collection across clusters
- Running business analytics on all of your telemetry data
- Avoid when:
 - You can have your control plane to query data directly on individual clusters
- Networking costs are a concern

Pattern #6 - Multitenant

Pattern #6 - Multitenant

Good for:

- Small deployments, where a central collector processes all the telemetry data for all tenants
- Central teams to handle telemetry backends for multiple departments
- Avoid when:
- You can have one entrypoint per tenant, avoiding a single point of failure

Pattern #7 - Per signal

Pattern #7 - Per signal

Good for:

• Isolating failures on production environments

Avoid when:

• You just need a simple deployment for your local dev or staging environments

Customizing OpenTelemetry Collector

Building your own distribution

- 1. manifest.yaml
- 2. opentelemetry-collector-builder
- 3. ???
- 4. Profit!

Building a component

- Config
- The component code, implementing one or more interfaces
- Factory

Building a processor

- Bootstrap go module
- Create a config.go
- Create a processor.go
- Add the processor logic
- Create a factory.go
- Bonus points: metrics.go

Key takeaways

Key takeaways

- OpenTelemetry has different subprojects in different areas
- The collector works as a middleware, abstracting the telemetry backends from your workloads
- It has tons of components for you to experiment with
- Mix and match collector instances with potentially different configurations
- Use the patterns from this presentation to derive your own patterns
- Extending the collector isn't that hard!
- Building your own distribution might be a good idea depending on your use cases

Thanks for attending!
